Cause: *Agrobacterium tumefaciens* (bacterium)

Hosts: Creeping euonymus, rose, willow, and poplar are particularly susceptible. This bacterium produces tumor-like growths on plant crowns, branches, and roots.

Management: Remove and destroy severely affected plants. Galled parts can be pruned off; disinfest tools frequently when pruning. Avoid replanting susceptible plants in areas where infected plants have been removed. The bacterium enters through wounds and can persist in the soil for many years after infected plants are removed. A commercially-available biological control agent, *Agrobacterium radiobacter*, can be used as a dip or spray to treat bare root plants, such as roses, before planting.
